

#### **Purpose**

This collection consists of:

Component	Purpose	
tJobInstanceStart	Register a job run and provide information about the previous job run.	
	Setup the logging facility.	
tJobInstanceEnd	Deregisters the job run, collects the metrics and cleans up the logging settings for this run.	
tJobDataRangeScanner	Collects min/max values of timestamps or numeric values within a data flows.	
tJobInstanceLiveCheck	Checks the entries of the job run registry for dead or broken job instances and cleans up the	
	job registry.	

These components help to track the execution of jobs in a database table.

Advantages of these components:

- Provides a unique numeric id for the job to mark all data sets processed by the job
- Start-/Stop timestamps
- Return code and error messages (collects all messages)
- · Host and PID of the process running this job
- Supports incremental loading
- Supports restart capabilities
- Key figures about moved data sets
- Snapshot of the context at the start and at the end of the job
- Detects the minimum and maximum of value for a flow
- Enables the usage and enhancement of Log4J in Talend jobs.
- Tracks the memory usage and detects peaks
- Detects parallel job runs (also based on the work item) and provide steering possibilities

## Talend-Integration

This component can be found in the palette under Management This component provides several return values.

### Component tJobInstanceStart

### **Basic Settings**

Property	Content	
Use data source (connection pool)	If true the component takes the database connection from a database connection pool.	
Data source alias	The name of the database connection pool providing the database connection.	
Database Connection	Any database connection pointing to the schema with the control tables.  The main table is JOB_INSTANCES holding all key information.	
Job Name	Name of the job. The default is using the build-in variable jobName	
Job Display Name	Human readable name of the job for reporting purposes	
Process Instance Name	Name of the process instance for reporting purposes	
Job Work Item	Text describing the work item (e.g. a file name or the date to process by this job)	
Take empty as null	If the given value is empty, it will be taken as null	
Time range start	If the job has to precede data selected by a time range. This could be used instead of a work	

Read ext. job instance id from variable.  Persist all context variables will be written as input values in the table: Job instance id from JOB_INSTANCE_CONTEXT  Load context from job instance (if 2-0)  Declare here a context variables containing a job instance id. If this ID is > 0 this job reads the context from this job instance. This provides restart capabilities to a job.  Singleton Behavior  Return last instance result  The last run is the last successful cast must have data inserted or deleted. The last run of this job instance. This provides will be detected via the key figures. See the properties of IJobInstancestart component.  Last successful The last run is the last successful run of this job (all others will be ignored)  Last must have data inserted or deleted. The swill be detected via the key figures. See the properties of IJobInstanceEnd.  For the current work item from the last value one job for multiple purposes with the full support of the "Return last instance result" feature.  Collecting job instances  Returns as comma separated list all instance ids of all jobs, which was running after the last run of this job. This helps to implement incremental jobs. It is necessary to write the job instance id into every data set proceed by the job.  Only successful Only successful job are part of the list above.  Only successful only job which affects more the one dataset will be part of the list above.  Filter the jobs which should part of the list above. This helps to keep the list small in case or having a lot of unrelated jobs in the system.  OK Result Codes  This is a String containing a comma-separated list of all return codes, which are related to a successful run. If you want using different return codes for OK please take care the tRunJob components does not die.  Replacement for prev. job should be provided feature to a previous job start date  These values can be used to simplify the job design because you can avoid the check if the job information  Job-instance-id Set here the Date typed def		item to see what work this job instance do.	
Write Job instance ID to See Value range start. This is the end of the range.  Write Job instance ID to Set here the context variable, which should contain the job by instance id.  Read process instance id in Sobs can combine to processes. In case of the job does not run as embedded job the process instance id an be read from a context variable. In case of need to identify a job via an external ID you can read it from this context variable.  Persist all context variables will be written as input values in the table: variables at start JOB_INSTANCE_CONTEXT  Load context from job instance (if > 0)  Bingleton Behavior See the section Singleton Behavior I ster in this document.  Last successful Last must have data Inserted or deleted See the properties of UobInstanceStart component.  Last successful The last run is the last successful run of this job (all others will be ignored)  Last must have data Inserted or deleted See the properties of UobInstanceEnd.  For the current work item will be used to get the last instance result. This allows you to have one job for multiple purposes with the full support of the "Return last successful run of this job (all others will be detected via the key figures. See the properties of UobInstanceEnd.  Collecting job instances  Returns as comma separated list all instance is of all job, which was running allows running after previous run  Colly successful Only job which affects more the one dataset will be part of the list above  Only with data  Only job which affects more the one dataset will be part of the list smale in the very data set proceed by the job.  ONF sesult Codes  Filter the jobs which should part of the list above. This helps to keep the list small in case of having a lot of unrelated jobs in	Time range end		
Write Job instance ID to Set here the context variable, which should contain the job instance id. Set here the context variable, which should contain the job instance id. Jobs can combine to processes. In case of the job does not run as embedded job the process instance if can be read from a context variable.  Read ext. job instance id In case of need to identify a job via an external ID you can read it from this context variable.  Persist all context variables at start  Load context from job instance id through the context variable will be written as input values in the table:  JOB_INSTANCE_CONTEXT  Load context from job instance id. If thus ID is ≥ 0 this job reads the context from this job instance. This provides restart capabilities to a job.  Singleton Behavior  Return last instance result  Last successful  The last run is the last successful run of this job. All information available as return values of the tolohistanceStart component.  Last successful  The last run must have data inserted or deleted. This will be ignored)  The last run must have data inserted or deleted. This will be detected via the key figures. See the properties of UobInstanceEnd.  Collecting job instances if run of this job for multiple purposes with the full support of the "Return last instance result" feature.  Collecting job instances if run of this job. This helps to implement incremental jobs. It is necessary to write the job instance in the overy data set proceed by the job.  Only successful  Only job which affects more the one dataset will be part of the list above  Only job which affects more the one dataset will be part of the list above  Filter the jobs which should part of the list above. This helps to keep the list small in case of having a lot of unrelated jobs in the system.  OK Result Codes  This is a String containing a comman-separated list of all return codes, which are related to a successful run. If you want using different return value PREV_JOB_INSTANCE_ID job-instance-id  Set here the Date typed default value f	Value range start	If the job has to precede a portion of data selected by an id range or any other value ranges.	
Set here the context variables, which should contain the job instance id.  Read process instance id from instance if can be read from a context variable.  Read ext. job instance id from a context variable.  Read ext. job instance id from a context variable will be written as input values in the table:  JOB_INSTANCE_CONTEXT  Load context from job instance id.  Declare here a context variable containing a job instance id. If this ID is > 0 this job reads the context from job instance (if >0)  Singleton Behavior  Return last instance  Return last instance  Fetches the information about the last run of this job. All information available as return values of the UbbInstanceStart component.  Last successful  Last must have data inserted or deleted  The last run is the last successful run of this job (all others will be ignored)  The last run must have data inserted or deleted. This will be detected via the key figures. See the properties of IobInstanceEnd.  Collecting job instances ids running after previous run  Only successful  Only job which affects more the one dataset will be part of the list above  Filter the jobs which should part of the list above.  Filter the jobs which should part of the list above.  This is a String containing a comman-separated list of all return codes, which are related to a successful run. If you want using different return codes for OK please take care the tRunJob components does not die.  Replacement for prev.  Job has a previous run. Please refer to the return values.  Set here a default long value for the return value PREV_JOB_INSTANCE_ID job-shart-date  Set here the Date typed default value for a previous job start date  time-range-end  Set here the String typed default value for a previous job cault item.  Set here the Estring typed default value for a previous provious itme zone cone to UTC. It affects the current JVM instance (means all job call	Value range end	See Value range start. This is the end of the range.	
instance if can be read from a context variable.  Read ext. job instance id lin case of need to identify a job via an external ID you can read it from this context from variable.  Persist all context variables will be written as input values in the table: JOB_INSTANCE_CONTEXT  Load context from job instance (if **)  Declare here a context variable containing a job instance (if .1 If this ID is > 0 this job reads the context from this job instance. This provides restart capabilities to a job.  Singleton Behavior  Return last instance result result values of the LobolistanceStart component.  Last successful The last run is the last successful run of this job. All information available as return values of the LobolistanceStart component.  Last must have data inserted or deleted. The last run is the last successful run of this job (all others will be ignored)  Last must have data inserted or deleted. This will be detected via the key figures. See the properties of LobolistanceEnd.  For the current work litem work allows you to have one job for multiple purposes with the full support of the "Return last instance result" feature.  Collecting job instances dids running after run of this job. This helps to implement incremental jobs. It is necessary to write the job instance id into every data set proceed by the job.  Only successful Only with data  Only successful job are part of the list above  Only with data  Only job which affects more the one dataset will be part of the list above  Onk Result Codes  Filter the jobs which should part of the list above. This helps to keep the list small in case of having a lot of unrelated jobs in the system.  This is a String containing a comma-separated list of all return codes, which are related to a successful run. Define here now to print the job instance in. Actuary it is not infined to the job instance in,	Expression to print	Define here how to print the job instance id. Actually it is not limited to the job instance id,	

## **Advanced Settings**

Schema	The schema (or database) will be retrieved from the connection object. In case of you want use a different schema or database, here is the place to say that.	
Table for job instances	The name of the main table. This table keeps all basic information about job runs. Usually it is called JOB_INSTANCE_STATUS. In case of this name violates existing tables or naming conventions, here it can be changed.  In former releases this table had the default name JOB_INSTANCES.  Starting with this release there will be no table renamed anymore because of the wide usage of this component.	
Job instance ID is auto increment	This have to be switched on if the table use an auto increment e.g. this is supposed for MySQL.	
Read from Generated Keys	If true, the component avoids to re select the job instance id instead it uses the jdbc driver feature to deliver the generated keys. Sometimes this does not work, and in this case deactivate this option.	
Sequence expression	In case of auto increment is off, here set the name of the sequences for the job instance ID. This expression has to return a new value for the job instance ID:  Examples:  MySQL: use auto increment  Oracle: job_instance_id_seq.nextval  PostgreSQL: nextval('dwh_manage.job_instance_id')  DB2: NEXTVAL FOR dwh_manage.job_instance_id_seq	
Table for job instance context	In this table the context variables will be saved. Usually it is called: JOB_INSTANCE_CONTEXT	
Table for job instance counters	In this table the named counters will be stored. Usually it is called:  JOB_INSTANCE_COUNTERS	

## Return values of tJobInstanceStart

Return value	Content
ERROR_MESSAGE	Last error message. Unfortunately this is not the error message from the actually running job. This message is build from the tRunTask component. The current TAC web service does not provide this message.
JOB_INSTANCE_ID	The job instance id used for this job run.
SOURCE_JOB_INSTANCE_ID_L IST	List of all job instance ids which are executed after the last run if this job. This way it is possible to implement incremental steering.  The list can easily be used in SQL e.g.:where job_instance_id in (" + ((String)globalMap.get("tJobInstanceStart_1_SOURCE_JOB_INSTANCE_ID_L IST") + ")"
JOB_START_DATE	The start date of the current job run.
PREV_JOB_EXISTS	If true means the job was running in the past at least one time.
PREV_JOB_START_DATE	If a previous job run exists (otherwise null): Contains the start date of the previous job
PREV_JOB_STOP_DATE	If a previous job run exists (otherwise null): Contains the stop date of the previous job
PREV_JOB_INSTANCE_ID	If a previous job run exists (otherwise null):

	Contains the ID of the previous job
PREV_JOB_TALEND_PID	If a previous job run exists (otherwise null): Contains the Talend-PID of the previous job
PREV_JOB_HOST_PID	If a previous job run exists (otherwise null): Contains the Host-PID (means the process ID of the operating system for this JVM) of the previous job
PREV_JOB_HOST_NAME	If a previous job run exists (otherwise null): Contains the name of the host where the previous job was running
PREV_TIME_RANGE_START	If a previous job run exists (otherwise null): Contains the time range start of the previous job
PREV_TIME_RANGE_END	If a previous job run exists (otherwise null): Contains the time range end of the previous job
PREV_VALUE_RANGE_START	If a previous job run exists (otherwise null): Contains the value range start of the previous job
PREV_VALUE_RANGE_END	If a previous job run exists (otherwise null): Contains the value range end of the previous job
PREV_JOB_RETURN_CODE	If a previous job run exists (otherwise null): Contains the return code of the previous job
PREV_WORK_ITEM	If a previous job run exists (otherwise null): Contains the previous work item of the previous job
PREV_RESULT_ITEM	If a previous job run exists (otherwise null): Contains the result item of the previous job
PREV_COUNT_INPUT	If a previous job run exists (otherwise null): Contains the count inserts of the previous job
PREV_COUNT_OUTPUT	If a previous job run exists (otherwise null): Contains the count outputs of the previous job
PREV_COUNT_UPDATED	If a previous job run exists (otherwise null): Contains the count updates of the previous job
PREV_COUNT_DELETED	If a previous job run exists (otherwise null): Contains the count deletes of the previous job
PREV_COUNT_REJECTS	If a previous job run exists (otherwise null): Contains the count rejects of the previous job

# Singleton Behavior

This component has the capability based in the information of the JOB\_INSTANCE\_STATUS table to detect already running instances of the same job (optional with the same work item). Here the necessary basic settings to use this feature:

Property	Content
Check if another job instance of the same job is already running	If true the component checks the JOB_INSTANCE_STATUS table for a already running job instance
Singleton for the work item	Use the work item to identify a job instance.
Prevent creating a job instance status entry if another job instance is already running	The option helps to avoid useless entries in the JOB_INSTANCE_STATUS table.

#### Dedicated return values

Return value	Content
JOB_RUNS_ALONE	The result of the singleton-check. This variable is not set if the check has not happened, this should help to prevent using this value if the actual check was not performed.
ALREADY_RUNNING_JOB_START_DATE	Start date (+time) of the already running job
ALREADY_RUNNING_JOB_INSTANCE_ID	The job instance id of the other job still running
ALREADY_RUNNING_JOB_HOST_NAME	On which server the other job instance is still running
ALREADY_RUNNING_JOB_HOST_PID	The native process id of the other job instance
ALREADY_RUNNING_JOB_WORK_ITEM	What work item the other job is still processing

## Component tJobInstanceEnd

## **Basic Settings**

Property	Content	
Use separate connection	If true: the end component uses a separate database connection. This could help for jobs running very long to avoid problems with long standing connections.	
Connection	Choose here the separate connection if you have chosen the option above. It must be a different connection component as used for the start component.	
Job Instance Start Component	Choose here the tJobInstanceStart component. Both components depend on each other.	
Job Result	A string representation of the result of the current job. In case the job creates a file it is a good idea to put here the file path.	
Time range start	If the job has to process data selected by a time range. This could be used instead of a work item to see what work this job instance do.	
Time range end	See Time range start. The end of the time range to proceed.	
Value range start	If the job has to process a portion of data selected by an id range or any other value ranges.	
Value range end	See Value range start. This is the end of the range.	
Save named counters	Counters can be named, in this case the counter value will be inserted in the table JOB_INSTANCE_COUNTERS	
Save context variables at the end of the job	This way it is possible to provide the context variables as output for other jobs, which are not embedded or running in different job servers or later. It is also useful for checks about the job result.	
Delete previous successful job instances by work item	If checked, the component deletes all successful previous job instances with the same work item. This helps in case of the table JOB_INSTANCE_STATUS will be used to keep track of the current data in the DWH and repeated job runs with the same work item replaces previous data.	
Close Connection	Closes the connection used for managing the job registration	
Input Counters	Counters describing the result of the job can be added here. The sum of all counters will be written in the JOB_INSTANCE_STATUS table in COUNT_INPUTS. The flag Add can be used to subtract a value instead of adding it. The name column provides the name (see Save named counters option)	
Output Counters	See Input Counters. Will be used for column COUNT_OUTPUTS	
Update Counters	See Input Counters. Will be used for column COUNT_UPDATED	
Reject Counters	See Input Counters. Will be used for column COUNT_REJECTED	
Delete Counters	See Input Counters. Will be used for column COUNT_DELETED	

As Counter typically the NB\_LINE return values of the input or output components can be used. In case of the job has more the one output it is recommended to set names for particular counters to keep the distinct counter values.

## Return values of tJobInstanceEnd

Return value	Content
ERROR_MESSAGE	Last error message.
RETURN_CODE	The retrieved return code of the current job
RETURN_MESSAGE	The created return message. This message contains all error messages from all components throwing an error.
MEMORY_AVAILABLE	This is the memory (in byte) what is maximum available for the job.  Typically it is set with the JVM parameter -Xmx1024m (e.g. for 1GB RAM)
MEMORY_MAX_USED	The maximum of the used memory (in byte) what was allocated in the JVM. Please keep in mind, if you call other jobs with tRunJob (not independently) they must be taken into account because they use the same JVM instance.
MEMORY_MAX_USED _PERCENTAGE	The percentage between the available memory and the maximum used memory as value between 0 and 100.

# $Component\ t Job Data Range Scanner$

# Basic settings

Property	Content
Job Instance Start Component	Choose here the tJobInstanceStart component. Both components depend on each other.
Schema	This is necessary to have the schema column available. It is not supposed to change anything here
Configure Extraction	For every schema column you can define for which range it will be checked: Time range or Value range. The min and max values will be found even the component runs in iteration.

## Return values

Return value	Content
ERROR_MESSAGE	Last error message in case of the range detection fails for a column.
TIME_RANGE_START	The min value for the measured time range.
TIME_RANGE_END	The max value for the measured time range.
VALUE_RANGE_START	The min value for the measured value range as Long or String
VALUE_RANGE_END	The max value for the measured value range as Long or String
NB_LINE_AGGREGATED	The number or rows for this component measured over all iterations

## Component tJobInstanceLiveCheck

This component checks if jobs still alive. To do this, you have to build a very simple job (checkout the scenarios) and let them run on every job server you have.

### **Basic settings**

Property	Content	
Database Connection	Any database connection pointing to the schema with the control tables.  The main table is JOB_INSTANCE_STATUS holding all key information.	
Close Connection	If true the connection will be closed at the end of the component processing	
Schema	This component provides an input flow providing information about cleaned job instances	
Last system start	If the last system start could be determined (currently there is not platform independent implementation to get this information automatically) all older job instance starts will be cleaned.	

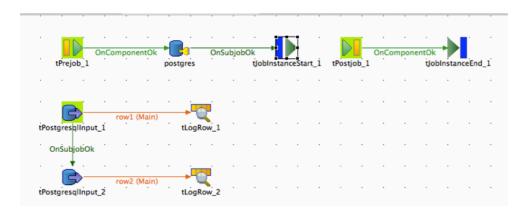

### **Return values**

Return value	Content
ERROR_MESSAGE	Error message if something in the processing of the component it self went wrong
COUNT_RUNNING_PROCESSES	The number of all running processes on the current server (regardless if this is a Talend job or not)
COUNT_RUNNING_JOB_INSTANCES	The number of as running declared job instances
COUNT_BROKEN_JOB_INSTANCES	The number of recognized broken job instances
NB_LINE	Number of rows in the data input flow

The schema is fully commented and provides the values of the JOB\_INSTANCE\_STATUS table for the broken instances.

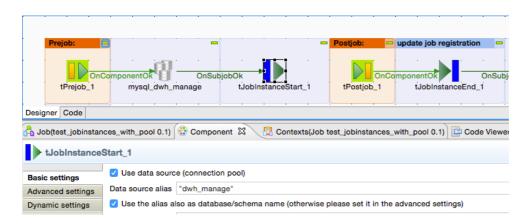

#### **Scenarios**

### Scenario 1: Simple Job monitoring

The typical usage is to use tPrejob component to trigger the tJobInstanceStart component and the tPostjob component to trigger tJobInstanceEnd component.

#### Scenario 2: Using a connection pool

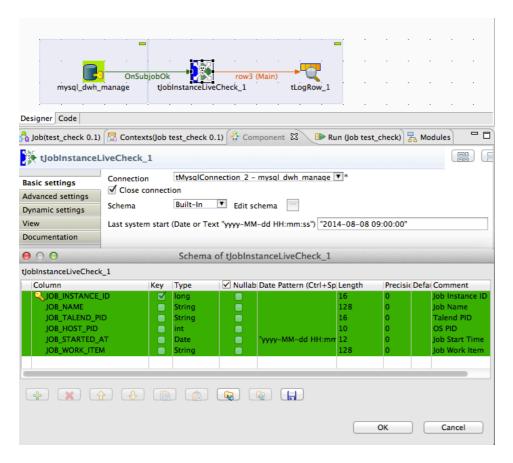

The connection pool can be established anywhere unless it is before the initialization of the tJobInstanceStart component. Also child jobs can use the same connection pool.

It is a good practice to name the pool like the addressed database. This way the configuration more convenient.

Scenario 3: Measure the time ranges and/or value ranges

In this Scenario the flow will be scanned for the start and end values for a time range and the value range. These values could be used to ensure the job quality or to start the next run from the previous end. Scenario for tJobInstanceLiveCheck

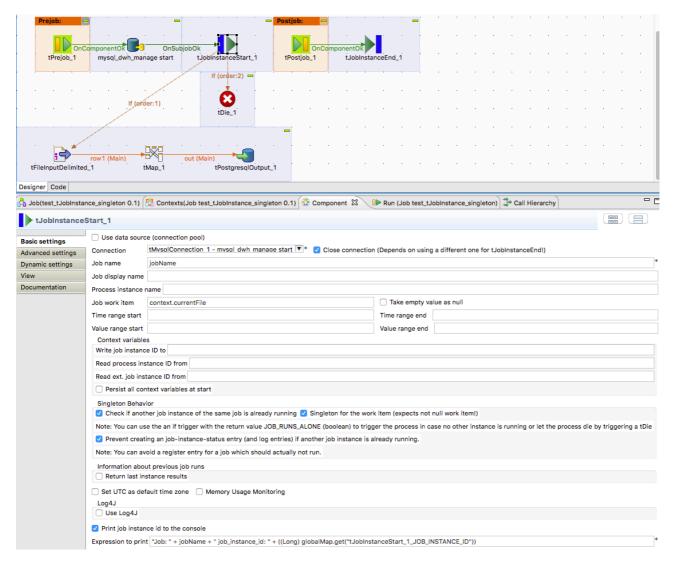

This example job shows the main purpose of the component. Such kind of job has to run frequently on every job server (servers on which the jobs run).

The component set for broken job instances the return code=999 and as return message "Process died". This information can be used to clean up all depending data structures.

### Scenario 4: Using the singleton check

The check depends in the information of the job\_instance\_status table. If you decide to use this check it is highly recommended to establish also a live check for job instances (use tJobInstanceLiveCheck component).

The if-trigger contains the return variable JOB RUNS ALONE to trigger the actual job or in this case to let the job die.

### Checklist to use this component suite

- Use a OLTP database for the tables used by this component. Column oriented database are mostly to slow for the possible high frequency insert/updates from a large number of simultaneous running jobs! Typical bad choices: Teradata, Infobright engine of MySQL... Typical capable databases: Oracle, MySQL, DB2, PostgreSQL, H2
- 2. Build a separate database schema (e.g. call it dwh\_manage or dwh\_meta or what you want ;-)
- 3. Think about the primary key in the JOB\_INSTANCE\_STATUS table. You can use a database sequence (this is the preferred way) or you can use a self-incrementing data type (e.g. serial or identity column types). If you use a sequence, please set the SQL code to get the next value in the advanced settings of the tJobInstanceStart component. By the way, in large projects it could be helpful to set these settings per default directly in the component in the tJobInstanceStart java.xml file of the component.
- 4. If you use the component, please check if the job is long running job and in this case use a separate connection for the tJobInstanceEnd component or consider the usage of a connection pool to avoid problems with server side disconnected database connections.

### Log4J Integration

The component contains a full-featured Log4J.

The component can initialize Log4J with a default configuration or by loading a configuration file.

A default logger called "talend" will be added to the logger hierarchy.

For every job a logger will be added with the name pattern: talend. <a href="mailto:Project">Project</a>. <a href="mailto:SJob Name">Job Name</a>

For every instance of a job an appender will be added (and removed at the end of the job).

Each appender is an extended FileAppender and transports only log events from its own job by filtering the events by the Talend-PID.

If the option "Write logs into log table" is switch on, for every job a second appender will be added (and removed) which sends the messages to the JOB\_INSTANCE\_LOGS table.

For the file output and the output to the table there a dedicated log formats.

✓ Set UTC as default time zone					
Log4J					
☑ Use Log4J					
Log4j config file  "/var/log/talend/log4j.xml"					
✓ Use a job log file					
Job log file pattern "/var/log/talend/{project}//jobName}_/jobInstanceld}.log" *					
Log file pattern layout "%-6r [%15.15t] %-5p %30.30c %x - [%X{origin}] %m%n"					
✓ Make context available for log output					
Use or share by name					
✓ Write logs into log table					
Log message layout pattern "[%X[origin]] %m"	×				
Submit messages in time interval [ms] (0 = commit immediately) 5000 Max. number message in queue until submit 100					
This setting affects this job and all further jobs in the same VM!					
☑ Catch System.out and System.err ☑ Forward messages to console					

The component adds to every event the context variables and all default information:

These additional values will be set as MDC key-value-pairs.

MDC values can be inserted in message pattern with the expression: %X{<key>}.

In file names (log-file names) the expression is simply: {<key>}.

Variable	Log message pattern (key)
Job name	jobName
Project	Project
Context	context
Job Instance ID	jobInstanceId
Talend job instance identifier	talendPid
Talend parent job instance identifier	talendFatherPid
Talend root job instance identifier	talendRootPid
Component which causes the message	Origin
Work item	workItem
tWarn or tDie priority	Priority
tWarn or tDie error code	Code
tWarn or tDie message type	type
Job version	version
Context variables	context. <variable></variable>
Timestamp of the job start in long format (yyyy-MM-dd HH:mm:ss.SSS)	jobStartTimestampLong
Timestamp of the job start in compact format (yyyyMMdd_HHmmss.SSS)	jobStartTimestampCompact
Job start date in long format (yyyy-MM-dd)	jobStartDateLong
Job start date in compact format (yyyyMMdd)	jobStartDateCompact

### Create table scripts for the tables

Not all databases are capable to work for this use case. Generally, all OLTP databases work fine. It could be problematic to host these tables on a column-based database or a database with distributed storage like Teradata. Such database tends to be very slow for single inserts and updates or they lock the whole table while such operations and this could lead to significant performance problems!

The well-tested databases are MySQL (MyISAM or INNODB), Oracle, PostgreSQL, H2 and IBM DB2 In case of MySQL it is recommended using a serial data type for the column JOB INSTANCE STATUS(JOB INSTANCE ID).

In the advanced settings of the tJobInstanceStart component it is possible to declare the schema and the table names. The option Job Instance ID is auto increment allows the usage of auto increment column for JOB\_INSTANCE\_ID in the table JOB\_INSTANCE\_STATUS. In former releases some tables had slightly different names but the meaning and structure is the same. You can adapt old names in the configuration if the tJobInstanceStart advanced settings.

#### MySQL (use auto increment)

```
